Key words:

Khasi mandarin, Macro-micro nutrients, Fertilizers, Tamenglong.

ABSTRACT

Extensive surveys were carried out covering as many as 40 orchards of Khasi mandarin in Thangal village of the sub-division Nungba under Tamenglong district in the year 2010-2011. Nutrient constraints in the form of N, P, Ca, Mg, Cu, and Zn were identified using these diagnostics which must find a due place in a fertilizer program of mandarin orchards of the region to obtain sustainable optimum fruit yield. The values of available nutrients viz., N, P, and K across 40 orchards varied from 92.2 to 348.2 mg/kg, 5.0 to 9.4 mg/kg, 110.0 to 440.1 mg/kg, respectively, with corresponding coefficient of variation (%) of 11.8, 9.2, and 16.4 respectively. Soil micronutrients showed a large variation of 11.2- 48.1 mg/kg Fe (CV 16.2%), 11.4-44.0 mg/kg Mn (CV 11.2%), 0.80-2.5 mg/kg Cu (CV 6.9%) and 0.50-2.8 mg/kg Zn (CV 7.4%). Leaf nutrient concentration like soil fertility showed a wide variation from 1.62-2.62 % N, 0.04-0.12% P, 0.72-1.89% K, 0.90-2.24% Ca and 0.28-0.61% Mg. Similarly, the micronutrients, namely Fe, Mn, Cu, and Zn expressed in ppm, varied from 118.4-282.3, 32.3-92.4, 1.0-3.8 and 14.6-28.4. It was observed that maximum nutrients are removed (in mg/tree) in the proportion of 171.90 N, 17.19 P, 34.38 K, 68.76 Ca, 17.19 Mg, 0.34 Zn and 0.20 Cu in relation to an average mean fruit yield of 34.38 (kg/tree) by Khasi mandarin i.e. orchard no. 1. Minimum nutrients are removed (in mg/tree) in the proportion of: 113.75 N, 11.37 P, 22.75 K, 45.50 Ca, 11.37 Mg, 0.22 Zn and 0.13 Cu in relation to an average mean fruit yield of 22.75 (kg/tree) by Khasi mandarin i.e. orchard no. 9. These observations give an insight about the order in which, different nutrients are preferred by specific citrus cultivar, and the ratio in which different nutrients are removed. Such nutrient removal patterns are to be meted out in order to maintain the sustained supply of the nutrients through soil.

INTRODUCTION

Globally, citrus is one of the important fruit crops being cultivated in an area of 3.35 million ha with a total production of 91 million tons. The current average productivity of citrus orchards in India is 8.9 tons ha⁻¹ compared to 4.52 tons ha⁻¹ obtained in northeast India (Srivastava and Singh 2002 a), the region historically believed to have witnessed the dissemination of citrus to other parts of the world. Cultivation of Khasi mandarin (*Citrus reticulata* Blanco) in northeast India is mainly confined to mid-hills upto an elevation of 1200 m above mean sea level under humid tropical climate. The highest quantum of production harvested globally is represented by soil orders viz., Alfisol, Oxisol, Ultisol, Entisol, and Inceptisol (Srivastava and Singh, 2002b).

Resultantly, the orchards continue to produce sub-optimally due to increasing gap between the amounts of nutrients added to that of annual demand with orchard age. The establishment of citrus orchards on steep slopes without contour trench planting or terracing has accelerated the menace of the problem by exposing the comparatively more acidic and infertile sub-surface having poor nutrient reserve to support the required nutrition of plants (Srivastava and Singh 2002 a). Of the different diagnostic tools leaf and soil- based nutrient standards have established their superiority over rest of the diagnostic methods. In the background of this information, the studies were carried out with the objectives viz. To determine the nutrient status and developing the fertilizer requirement.

MATERIALS AND METHODS

Extensive surveys were carried out covering as many as 40 orchards of Khasi mandarin in Thangal village of the sub-division Nungba

under Tamenglong district in\ the year 2010-2011. Tamenglong district's topography is made up of mostly of rugged hills, lofty mountains and rolling valleys with occasional human habitation in the bucolic hamlets. The district encompasses an area of 4391 sq. km. and stretches across the latitudinal parallel to 24^{0} 59' north and the longitudinal meridian of 93^{0} 30' east. The present study was carried out in one experimental locations i.e. Thangal village under Nungba sub-division. The geographical co-ordinates of Nungba is latitude 24^{0} 45'0" North, longitude $93^{0}26'0$ " East. The mean summer and mean winter temperature of this region vary from $31\Box C$ and $4\Box C$ and annual rainfall of 3135 mm with relative humidity 76% (minimum), 92% (maximum).

Soil and leaf sampling

Soil samples were collected from skirt belt/perimeter of trees, the zone having maximum concentration of feeder roots at soil depth of 0-20 cm. Likewise; the leaf positions from non-fruiting terminals covering 2-10% trees at a height of 1.5-1.8 m from the ground were sampled.

Analytical methods

Collected soil samples were air dried, ground, and passes through 2mm sieve, and subjected to analysis of available nitrogen using Alkaline Permanganate Method (Subbiah and Asija, 1956), Bray-P using ammonium fluoride extraction by shaking 1g

soil in 20 ml of 0.03 (N) NH₄F in 0.025 N HCl for 30 min., Ca, Mg, and K extractable in 1 N neutral NH₄OAc in 1:2 soil: extractant ratio after shaking for 30 min. (Lanyon and Heald, 1982) and micronutrients (Zn, Cu, Mn and Fe) in 0.05 M (pH 7.3) DTPA-CaCl₂ after shaking 20g soil and 50 ml extracatant together for 2 hours (Linsay and Norvell, 1978). Leaf samples were thoroughly washed (Chapman 1964) and ground using a Wiley-Grinding machine to obtain homogenous samples. Tri-acid (HClO₄: HNO₃: H₂SO₄ in 2:5:1) extracts of leaf samples (Chapman and Pratt 1961) were subjected to analysis of P using vanadomolybdophosphoric acid (ammonium molybdate + ammonium metavanadate) method, K flame photometrically, Calcium and magnesium by versene titration (Lanyon and Heald 1982) using ammonium purpurate (murexide) and erichrome black-T as indicators for Ca and Ca+ Mg, respectively, and micronutrients by Atomic Absorption Spectrophotometer. While, total N in leaves was determined using auto-nitrogen analyzer.

RESULTS AND DISCUSSION

Available macro and micro nutrients in the soil

Optimization of soil properties is an emerging field of investigation. It represents a new stage in managing soil fertility in which the transition is made from simple improvement of soil properties to regulation of these properties aimed to bring them into agreement with plant needs in order to achieve maximum yields (Srivastava and Singh 2001a, 2001b). The values of available nutrients viz., N, P, and K across 40 orchards varied from 92.2 to 348.2 mg/kg, 5.0 to 9.4 mg/kg, 110.0 to 440.1 mg/kg, respectively, with corresponding coefficient of variation (%) of 11.8, 9.2, and 16.4 respectively. The mean values of N, P, K, Ca and Mg were observed as 180.5, 7.0, 196.1, 156.8 and 36.5 mg kg⁻¹ respectively (Table 1). This results are similar to those in the book entitled "Citrus in NEH Region" authored by Singh *et al.* (2006).

Total number of units/observations = 40

The mean values of Fe, Mn, Cu, and Zn were observed as 28.7, 21.2, 1.4 and 0.8 mg kg⁻¹. Micronutrients likewise showed a large variation of 11.2- 48.1 mg/kg Fe (CV 16.2%), 11.4-44.0 mg/kg Mn (CV 11.2%), 0.80-2.5 mg/kg Cu (CV 6.9%) and 0.50-2.8 mg/kg Zn (CV 7.4%) (Table 2). This results are similar to those in the book entitled "Citrus in NEH Region" authored by Singh *et al.* (2006).

Leaf macro and micro nutrients composition

Validity of the leaf analysis as an instrument for controlling the mineral nutrition is related to the significance, the total concentration in the leaf gives a precise image of the production output of crop and its dependence on the supply of each nutrient. Leaf nutrient concentration like soil fertility showed a wide variation from 1.62-2.62 % N, 0.04-0.12% P, 0.72-1.89% K, 0.90-2.24% Ca and 0.28-0.61% Mg. The mean values of N, P, K, Ca, Mg were observed as 2.1%, 0.09%,

1.4%, 1.76% and 0.62% respectively with corresponding coefficient of variation (%) of 15.45, 29.02, 28.47, 21.14 and 36.35 respectively (Table 3). Earlier studies (Srivastava and Singh 2001c,2003a) using Nagpur mandarin (*Citrus reticulata* Blanco) as test crop grown on Ca rich alkaline montmorillonitic black clay soils under hot sub-humid tropical climate of central India showed similar kind of delineation of nutrient levels having statistically significant difference in relation to fruit level. Under similar growing conditions, Ko and Kim (1987) suggested optimum leaf N, P, K, Ca, Mg as 2.5-2.8, 0.19-0.20, 1.5-1.7, 2.5-3.0, and 0.30-0.35 % respectively, for Satsuma mandarin grown in Jeju Island of Korea.

Fruit nutrient removal

A significant amount of nutrients is removed by the citrus fruits. It was observed that maximum nutrients are removed (in mg/tree) in the

proportion of: 171.90 N, 17.19 P, 34.38 K, 68.76 Ca, 17.19 Mg, 0.34 Zn and 0.20 Cu (Table 3) in relation to an average mean fruit yield of 34.38 (kg/tree) by Khasi mandarin i.e. orchard no. 1.

Minimum nutrients are removed (in mg/tree) in the proportion of : 113.75 N, 11.37 P, 22.75 K, 45.50 Ca, 11.37 Mg, 0.22 Zn and 0.13 Cu (Table 5) in relation to an average mean fruit yield of 22.75

Table 4. Leaf nutrient composition in relation to fruit yield in Khasi mandarin orchards in Manipur

10.	23.30	116.50	11.65	23.30	46.60	11.65	0.23	0.13

(kg/tree) by Khasi mandarin i.e. orchard no. 9. These results are accordance with the findings of Srivastava and Singh (2004a). These observations given insight about the order in which, different nutrients removed by the citrus crop is required to replenish in the soil to sustain the productivity which are preferred by specific citrus cultivars in the ratio in which different nutrients are removed. Such nutrient removal patterns are to be meted out in order to maintain the sustained supply of the nutrients through soil which will lead to sustain the productivity to the citrus cultivar of Manipur.
