Resource degradation,  
Resource use Management.

### ABSTRACT

Sustaining agriculture and food security in the face of serious and widespread problems of resource degradation and more ominous climate change related issues has emerged as a major challenge of the present century. In the past most interventions to enhance agriculture have aimed at improving crop yields through the supply of seed improved cultivation and inputs and little consideration has been given to sustainable resource use management. A small study was conducted in the Mewat district of Haryana, India with an objective to examine is as to what extent the past agricultural development efforts and technological interventions has benefitted the region considering the associated impact which these interventions entailed on the state of natural resources. The study has clearly indicated that past agricultural development has significantly impacted natural resource base of the region specifically groundwater and the soils of the region. Thus it has been observed that declining availability and quality of ground water resource, widespread problem of soil degradation, lack of fodder and feed resource for the livestock, and fuel for household would appear the key entry points where the activities of different agencies must complement to yield sustainable gains in livelihood opportunities.

## INTRODUCTION

Sustaining agriculture and food security in the face of serious and widespread problems of resource degradation and more ominous climate change related issues has emerged as a major challenge of the present century. Agriculture being the major land use and a source of livelihood for more than 58% of India's population, agricultural scientists' community has a critical role in developing and promoting strategies and agricultural practices aimed at sustained benefits with reversing processes contributing to resource degradation and adapting to climate change. Resource degradation issues exacerbated by uncertain climatic events directly impacts agriculture and the livelihoods of the farmers. Particularly risk prone and adversely impacted are the farming communities in rainfed and resource depleted regions and where the past agricultural development efforts have not yielded the desired gains. It is in this context that the Planning Commission has identified 150 most backward districts in the country with a view to reinforce focused efforts towards improved livelihoods. Mewat district of Haryana forming a part of the dry semi-arid ecoregion spread over the states of Haryana, Rajasthan and western Uttar Pradesh is one of the least developed districts in Haryana (Planning Department, Government of Haryana, 2011). Agriculture being the major land use and farming the main vocation for livelihood for majority of the population in the region, it is thus important to understand the current dynamics of resource use and agriculture related activities such that any interventions aimed at enhancing agriculture productivity ensure sustainable resource use and management while improving livelihood opportunities. Apart from the baseline understandings of the bio-physical and socio-economic characteristics of the region; analyzing past developmental and technological interventions is extremely important in order to assess the accrued benefits of these initiatives and for exploring

sustainable developmental and technological options for the current and future. These were the primary objectives of this study.

### Study Area

Mewat-a part of the North Punjab plain, Ganga-Yamuna Doad and Rajasthan upland hot dry semi-arid eco-subregion accounts for an area of 118 million ha representing nearly 36.5 % of the ecoregion and 3.5 % of the total geographical area of the country. The length of growing period in the subregion varies between 90 and 120 days beginning with July and ending with the first fortnight of October (Gajbhiye, and Mandal). Earlier, a part of Gurgaon and Faridabad districts, Mewat was carved out as an independent 20<sup>th</sup> district of Haryana state in April 2005. The district has two tehsils Nuh and F. P Jhirkha with five development blocks namely Taoru, Nuh, Nagina, F. P Jhirkha, and Punhana (Mewat CDAP, 2007).

## METHODOLOGY

The study is a part of World Bank funded, Indian Council of Agricultural Research, National Agricultural Innovation Project, 'Achieving improved livelihood security through resource conservation and diversified farming system in Mewat'. Following methodology was adopted for achieving the objectives of this study.

- **Literature Review:** literature review of both the research papers and other documents (publications by NGOs, reports of line departments, reports of other government agencies) has been done to build a sound understanding on major issues impacting sustainability of agriculture in the district and to explore possible options and opportunities available to facilitate actions towards sustainable agriculture.
- **Stakeholder Interactions:** to supplement understanding gained through literature review interactions with key stakeholders (farmers, official of line department, officials of major

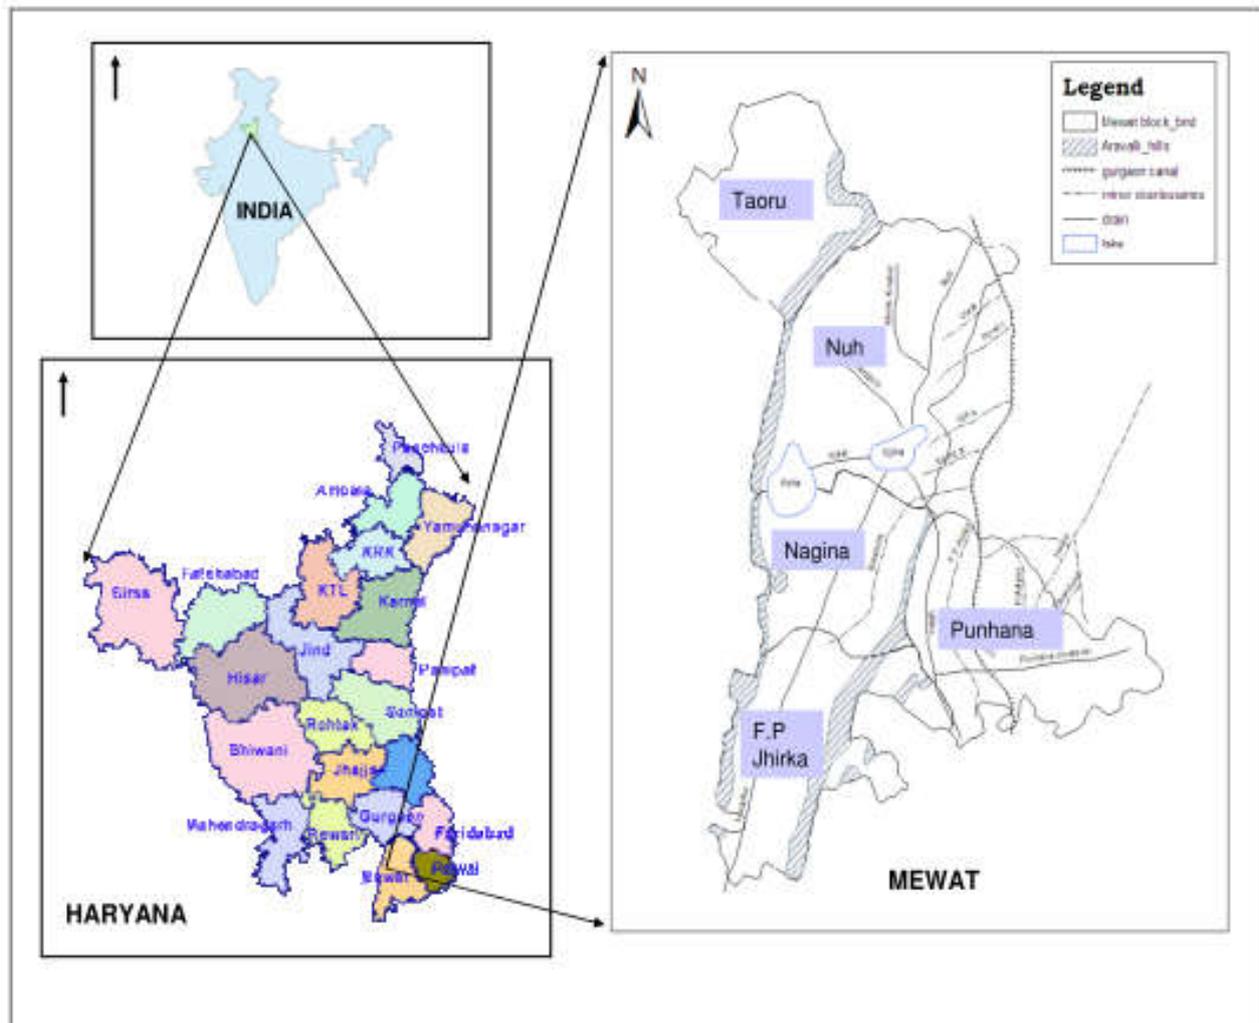

Fig. 1. Location of Mewat

organizations working in the district, officials of Central Groundwater Board (CGWB), officials of Haryana Agricultural University, and Haryana Space Applications Centre) have been done. The understanding was further crystalized by the information gained through various stakeholder consultations/meetings carried out by various agencies (Annexure I).

## RESULTS AND DISCUSSIONS

### Current dynamics of resource use and agriculture related activities in the district

The factors governing the dynamics of resource use and agriculture are both bio-physical and socio-economic in nature. Thus both the factors were analyzed separately; the details are listed in Table (1) and Table (2).

### Past Agriculture Development Efforts

Over the recent past considerable efforts has been made at the state level to improve agriculture productivity of the region. Development efforts of the region are being coordinated by Mewat Development Agency (MDA), while different line departments of the government are the executing agencies. From 1995-2005, MDA executed a major project funded jointly by International Fund for Agricultural Development (IFAD) 67% and Govt. of Haryana 29% with the objective of improving the social and economic well being through

promoting activities which aimed at greater self resilience on a sustained basis while broadening the range of economic opportunities available to the communities. Although the project came to an end in 2005 at which time Mewat was also carved out as a new district of Haryana many of the activities have since been pursued by different line departments through Central and State government funded projects. Table (3) above provides a brief summary of the broad activities that have been or are being pursued towards agricultural and related developments. The key question that we wish to examine is as to what extent the benefits of past agricultural development efforts, and the technological elements which formed a basis, can be sustained considering the associated impact which these interventions entailed on the state of natural resources and if the agricultural practices promote during the project phase can be pursued on a sustained basis by the farmers in the absence of specific project based interventions in the post project phase.

### Major Findings

#### Efforts to address issues of soil and water conservation:

These efforts have been pursued through two separate approaches one adopted by division of Soil and Water Conservation, Department of Agriculture focusing mainly on engineering approaches while the other being a part of the crop production strategy and being pursued by the agriculture department. Establishment of water harvesting structure/percolation tanks along periphery of Aravalli fort hills together with construction of field bunds check dams gully plugs, diversion bunds to check erosion etc being the main activities. There are serious question on sustainable benefits

<ul style="list-style-type: none"> <li>Increased awareness and know-how about improved crop production and efficient input-use technologies</li> </ul>	<ul style="list-style-type: none"> <li>Organize crop (wheat, mustard, millet etc.) demonstration plots to demonstrate potentials of new cultivars and total package of technologies.</li> <li>Demonstration of farming techniques in relation to crop production (double/ multiple cropping opportunities, pest control equipment, benefits of green manuring.</li> <li>Training, on farm research trials, study visits etc.</li> </ul>	<ul style="list-style-type: none"> <li>Enhanced crop productivity through the adoption of improved cultivars, crop management practices and crop diversification.</li> </ul>
<ul style="list-style-type: none"> <li>Livestock Improvement</li> </ul>	<ul style="list-style-type: none"> <li>Infrastructure developing facilities by way of livestock development complexes (16), establishment of mini dairies (36), milk booth (8), mil chilling centre (2).</li> <li>Facilitating establishment of dairy cooperative societies.</li> <li>Supply of mineral supplements and organizing deworming of livestock for improved health.</li> </ul>	<ul style="list-style-type: none"> <li>Increased milk yield and income of farmers.</li> <li>Reduced causalities and incidence of diseases.</li> </ul>

accruing from these efforts. While enhanced percolation of harvested water aiding in recharge of groundwater has been the main plank to justify the investments, there have been no serious evaluation studies particularly in term of temporal changes in percolation rates in relations to silting of the tanks, maintenance longevity and upkeep of the structure etc. It is also little appreciated that activities like field bunding, check dams are cost intensive, do not in any way reduces or help water erosion and in any case there has never been a doubt that their maintenance is always a casualty. There have been very little if any efforts aimed at promoting such simple practices as vegetative barriers, wind breaks, and mulch etc. which farmers can themselves pursue with relatively little advisory back up.

- **Crop production programs:** (a) these programs have long recognized declining soil health and quality as critical to sustained productivity. It is also recognized that how organic matter content of the soil is most critical to overall health of soils including its physical, chemical, and biological properties yet the major focus of efforts to address soil related constrains has been on meeting the needs through chemical fertilizers which are needed in over increasing quantities and to include an increasing range of macro, secondary, and micro nutrient to maintain crop yields incurring higher input costs. Very little efforts has made to develop and promote practices which might have the potential of improving carbon status of soils-the key determinant of soil quality over the past decades or so growing of sesbania for green manuring has been promoted by providing seeds etc at subsidized rate and this practice is being adopted widely. Again the main reason for its wide acceptations is its ability to contribute a significant amount of nitrogen needs. Gypsum as a soil corrective (amendment) to restore soils' loss of productivity on accounts of adverse effects of use of poor quality groundwater for irrigation is yet another intervention being promoted to maintain soil quality. (b)The singular focus of crop production related interventions (improved cultivars, alternate crops) has been to raise crop yields with increased use of inputs (water, fertilizer, pest control chemicals etc.) with little emphasis on cost consideration, use efficiency of inputs and quality of the resource base. As a result productivity increase has been achieved at a cost in term of resource degradation limiting sustained gains. It is thus apparent that perusal of resource conservation and crop production strategies in isolation has brought us face to face with a situation where achieving further gains is ridden with unimagined challenges.
- **Livestock improvement programs:** This is another major opportunity to improve livelihoods of the people of the region. Again challenges of livestock improvement are linked closely to cropping activities and to available adequate nutrient fodder. While crop production strategies have little focus on availability of fodder, livestock activities have largely focused on issues of genetic improvement through artificial insemination, control of diseases, and milk processing etc. Thus what is needed is to put in place more integrated approaches which can take into account the strong linking's which exist between the crop and livestock sections on the one and productivity and resource conservations concerns on the other.

## Conclusion

An overarching requirement in the generation and promotion of technologies to achieve the somewhat elusive sustainability goal in the high degree of spatial variability in resource endowments superimposed by high spatial and temporal variability in seasonal climatic episodes which makes technological needs highly specific to a location, thus developing, adapting and promoting technologies to match the natural resource variability (groundwater quantity, quality, soil characteristics) and climatic episodes which simultaneously address issue of cost reduction, productivity increase while making

efficient use of input and maintaining or enhancing the quality of resource base is an imperative which can no longer be ignored if sustainable productivity gains are to be achieved. This will also call for a shift in focus from evaluating gains from technologies purely in terms of individual yield increases to evaluation that consider total biomass, including livestock and household fuel needs. This will also then call for a shift in focus of technologies needs, of not only what the farmers themselves can do at their own fields but on the community action needs which extends to beyond their own fields to the needs of what needs to be done in relation to community lands and watershed/landscapes as a while. In short the need to increasingly build up a system perspective in defining and seeking technologies option for improving the livelihood opportunities for people in the region.

An important imperative in this regard is the opportunity to build upon the strong accumulated knowledge base of the farmers and farming communities of local resource issues and their dynamic understanding over spatial and temporal dimensions. It is in this context that identifying interventions and adapting them under specific farming situations working together with farmers provides an opportunity for greater likelihood of uptake of technological interventions. This is in contrast to the conventional approach whereby standardized technologies packages are recommended for adoption. This calls for a strong component of adaptive research which can serve to bridge the existing large divide between the scientific community and farmers on the one and with development agencies on the other. This also brings to the fore the need for ensuring a strong complementarity between the efforts of the line development departments in achieving objectives. Thus if improving livelihoods while enhancing resource use efficiency and resource quality are the key objectives there has to be a strong complementarity between the activities of departments. This will happen when the prioritizations of interventions of different departments are derived from the same common objectives eg. improved livelihoods while ensuring long-term sustainability of resource use and quality. In the case of Mewat the resource base, limitation of declining availability and quality of available ground water resource, widespread problem of soil degradation through erosion, soil salinization and waterlogging and depleted soil fertility and the lack of fodder and feed resource for the livestock and fuel for household would appear the key entry points areas where the activities of different agencies must complement to yield sustainable gains in livelihood opportunities.
