ABSTRACT

Impatiens are commonly known as ‘Balsams’ (Jewel weeds). *Impatiens* L. is one of the largest genera of flowering plants. Among 850 species found in the tropics and north temperate regions. 86 species reported from the Western Ghats, 76 are found to be endemic. Bryophyte, wild *Impatiens* and some Pteridophytes are more sensitive environmental indicators. They survive well in adjoining fresh water seeping habitat. Endemic plants association depend one another to maintain their micro climate and ecosystem. So neighborhood population study helps to conserve endemic plants. This study shows Bryophyte population also helps to *Impatiens levingei* succession in untainted environment. 13 endemic species placed in the study area.

INTRODUCTION

Impatiens levingei is the widespread genera of Balsaminaceae family in Angiosperms. *Impatiens* group plants generally known as ‘Balsams’ (Jewel weeds). Some *Impatiens* are cultivated as ornamental and some are used in medicine and cosmetics. *Impatiens levingei*. is one of the largest genera in flowering plants comprises 850 species found in the tropics and north temperate regions (Mabberley, 1993) among 210 species represented in the Eastern Himalaya and the Western Ghats. Both regions show a high degree of endemism (Mittermeier et al., 2004). 86 species reported from Western Ghats in that 76 were found to be endemic (Nair 1991). Two groups of *Impatiens* occurring in India one group had short swollen spindle shaped pods distributed in peninsular region other one group had long and narrow pods distributed in the Himalayan region (Hooker 1874). Seeping springs water areas are the natural habitat of *Impatiens*. These areas shows abnormal habitat type differ from other habitat and interesting subject to study species environment relationships. More sensitive environmental indicators of Bryophyte, wild *Impatiens* and some Pteridophytes are survives well in fresh water adjoining habitat and grassland. Direct interaction of Bryophytes includes providing food, shelter and nesting material for small mammals and invertebrates. Indirectly, they serve as a matrix for a variety of interaction between Organisms (Srivastava and Alam, 2005).

Seeping spring water habitat shows clear variation from the neighborhood habitats. Springs natural drivers for ecosystem functioning. According to Frahm and Klaus (2001) Terrestrial lower life forms are ecologically very important grow in a variety of life forms due to they are component of montane forest ecosystem. Bryophyte has high degree of soil binding capacity and water holding capacity (smith, 1982; Richards, 1984). Interaction between herbaceous life forms in spring water habitat helps to neighborhood species succession. So neighborhood population study helps to conserve endemic *Impatiens*.

MATERIALS AND METHODS

Study area: Three natural habitat locations of *Impatiens levingei* were selected for population study. They are Lamb’s Rock (Shola forest) (11°21'03"N 76°49'14"E), Droog (Grassland) (11°18'43"N 76°49'01"E), Carrington (Grassland) (11°12'59"N 76°36'56"E). 1m×1m size of 20 quadrates were selected in each locations to study herbaceous population. The collected specimens were identified by standard keys as following. Gamble (1935), Fyson (1915), Hooker (1872-1897) were used for Angiosperms identification. Beddome (1830 - 1911), Baynes (1887), Manickam and Irudayaraj (1992) were used for Pteridophyte identification. Gangulee (1957, 1959, 1969 – 1980), Afroz Alam (2011), (2012) were used for Bryophyte identification.

RESULTS

In the natural habitat of *Impatiens levingei* over all 54 plant species were found in the herbaceous layer. It includes 34 family. The dominant family found in the study area is Lamiaceae, Orchidaceae, Poaceae each family consist 4 species

Isodonwightii (Benth.) H.Hara,
Anisochilussuffruticosus Wight,
Leucasrosmarinifolia Benth,
Pogostemonnilagiricus Gamble,
Aeridescrispia Lindl,
Coelogyne nervosa A.Rich,
Habenarialongicornu Lindl,
Phyllorchisnilgherensis (Wight) Kuntze,
Cymbopogonflexuosus (Nees ex Steud.) W.Watson,
Isachneunthiana (Wight & Arn. ex Steud.) Miq,
Panicumgardneri Thwaites,
Themedatriandra Forssk respectively (Table1).

Graph 2 shows Droog had second leading population of *Impatiens levingei* 30.03% in 70.01% of Angiosperm population here Bryophyte population is 19.18%. Droog shows second leading population of *Impatiens levingei* 5.58% in 77.92% of Angiosperm population here Bryophyte population is 15.19%. *Selaginella radicans* Hort. ex Alston, *Adiantum raddianum* C. Presl, *Nephrolepis auriculata* Trimen, *Stegnogramma pozoi* (Lag.) K. Iwats. *Deparia petersenii* (Kunze) M. Kato are the Rayne ferns collected in Lamb's rock. Endemic fern *Selaginella radicans* associated with *Impatiens levingei*. *Aerides crispa* Lindl, *Anisochilus suffruticosus* Wight, *Coelogynne nervosa* A. Rich, *Heracleum rigens* Wall. ex DC, *Impatiens cuspidata* Wight & Arn, *Impatiens levingei* Gamble ex Hook.f, *Isodon wightii* (Benth.) H.Hara, *Kalanchoe grandiflora* Wight & Arn, *Leucas rosmarinifolia* Benth, *Ophiorrhiza brunonis* Wight & Arn,

Osbeckia leschenaultiana Wight, *Pogostemon nilagiricus* Gamble, *Selaginella radicans* hort. ex Alston are the endemic species placed in the study area. Figure 2 shows entire habit of *Impatiens levingei*. Figure 3 shows total population of *Impatiens levingei* was 16.82% in 72.75% of Angiosperms.

DISCUSSION

According to Thangavelu et al., 2015 *Impatiens levingei* were neighborhood with *Malaxis nilgiriensis* grows mixed with *Malaxis versicolor*, *Anaphalis neelgerryana* Sch.-Bip.ex (DC.) DC., *Calanthe sylvatica* (Thouars) Lindl., *Eriocaulon odoratum* Dalz., f., *Malaxis rheedei* Sw, *Persicaria chinensis* (L.) Gross and *Persicaria nepalensis* (Meisner) H. Gross in Mukurthi National Park. *Impatiens levingei* and orchids succession is high in pollution free seeping spring water and

Graph 1: Population comparison of *Impatiens levingei* with neighborhood species

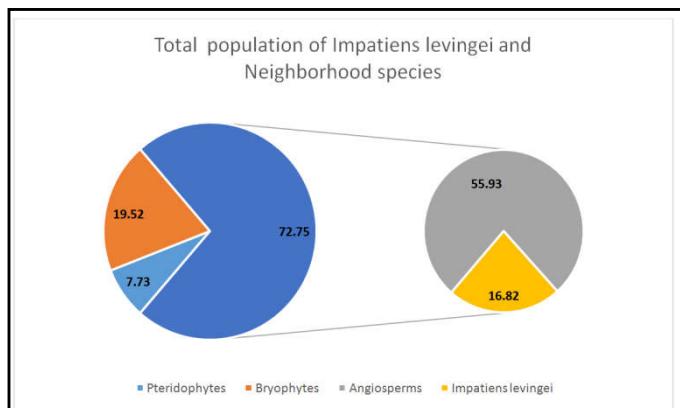

Figure 3: Total population of *Impatiens levingei* and Neighborhood species

grassland ecosystem. *Impatiens levingei* was collected by Gamble in 1883 from Lamb's Rock Shola forest (study area). Link address: <http://apps.kew.org/herbcat/getImage.do?imageBarcode=K000694893>. Three new taxa of *Impatiens* L., viz. *I. kawtyana* sp. Nov., *I. taimushkulni* sp. Nov. and *I. nilgirica* Fisch. var. *nawtyna* var. nov. are described from southern Western Ghats of Tamil Nadu, (Tarun Chabra *et al.*, 2016.) *Impatiens rufescens* endemic reported from upper Nilgiri swamps in wetland habitat and narrow geographical range. It is very sensitive and once their habitat is lost or altered, they are usually unable to recover (Mohandass 2008). All endemic impatiens are very sensitive they are the indicators of untainted environment. Rajeev Kumar 2016 referred *Impatiens levingei* as endemic plant to Western Ghats. According to Sahu *et al.*, (2007). Bryophytes are used as bio indicators for environment pollution because they are very sensitive. Water retaining capacity of Bryophytes helps the luxuriant growth of *Impatiens levingei* in spring water seeping area of Lamb's Rock. Because of this property the population dynamics of both Bryophyte and *Impatiens levingei* is faster in shola compared to grasslands. Impatiens and Bryophytes are mostly very sensitive plants groups. They are growing well in shady water dripping habitat like Lamb's Rock Shola forest. But in grasslands of Droog and Carrington they are not able to grow successfully. This study shows *Impatiens levingei* and Bryophyte population depends one another.
