## INTRODUCTION

Fixed point theory is among the fundamental tool of nonlinear functional analysis. Banach (1922) showed that every contraction mapping on a complete metric space always possess a unique fixed point. This study focused on proving the existence and uniqueness of common fixed points of f-contraction mapping defined on complete metric spaces endowed with a partial order by using generalized altering distance functions. I tried to answer the question how can we prove the existence and uniqueness of common fixed points of f-contraction mappings defined on complete metric spaces endowed with a partial order by using generalized altering distance functions satisfying occasionally weakly compatible?. Su (2014) proved the following fixed point theorem, which is the generalized type of Yan et al. (2012); Let ( $\mathrm{X}, \preccurlyeq$ ) be a partially ordered set and suppose that there exists a metric din X such that ( $\mathrm{X}, \mathrm{d}$ ) is a complete metric space. Let $\mathrm{T}: \mathrm{X} \rightarrow \mathrm{X}$ be a continuous and non-decreasing mapping such that
$\eta(d(T x, T y)) \leq \phi(d(x, y)), \forall y \preccurlyeq \mathrm{x}$,
where $\eta$ is a generalized altering distance function and $\phi:(0, \infty) \rightarrow(0, \infty)$ is a right uppersemi-continuous function with the condition: $\eta(t)>\phi(t)$ for all $t>0$.If there exists $x_{0} \in X$ such that $x_{0} \leqslant T x_{0}$, then T has a fixed point. Many results appeared related to fixed point theorem in complete metric spaces endowed with a partial ordering $\leqslant$ in the literature (Amini-Harandi, 2010; Naidu, 2013; Suzuki, 2008; Yan, 2012). Inspired and motivated by the results mentioned on (Su, 2014), I extend the main theorem of ( $\mathrm{Su}, 2014$ ) to f-contraction mapping in a complete metric space endowed with a partial order by using generalized altering distance functions satisfying occasionally weakly compatible maps and proved the uniqueness of the common fixed point obtained. Examples are given to show that my results are proper extension of the existing one. In (Arvanitakis, 2003; AminiHarandi, 2010; Beg, 2006; Boyd, 1969; Chidume, 2002; Choudhury, 2000), the researchers proved some types of weak contractions in complete metric spaces. In particular the existence of a fixed point for weak contraction is extended to partial ordered metric spaces under the works of (Amini-Harandi, 2010; Choudhury, 2000; Tesfaye Megerssa Oljira, 2012).

[^0]
#### Abstract

In this paper, common fixed point theorems of f-contraction mapping have been established with generalized altering distance function. Existence and uniqueness of common fixed point offcontraction mapping with generalized altering distance function in partially ordered metric spaces satisfying occasionally weakly compatible maps are proved.

Definition 1.1 (Tesfaye Megerssa Oljira, 2019) A function $\eta:[0, \infty) \rightarrow[0, \infty)$ is called an altering distance function if the following properties are satisfied:
a. $\eta$ is continuous and monotonically non-decreasing.
b. $\eta(t)=0$ if and only if $t=0$.

## Example The following function is an altering distance function:

$\eta(t)=\left\{\begin{array}{l}0, \quad t=0 \\ \beta t, \quad t \geq 1,\end{array}\right.$ where $\beta \geq 1$.
Altering distance functions have been used in metric fixed point theory in a number of papers. Some of the works utilizing the concept of altering distance function are noted in (Babu et al., 2007; Choudhury, 2005; Khan, 1984; Sastry, 1999) (Babu et al., 2007; Choudhury, 2005 Khan et al., 1984; Sastry et al., 1999).

Definition 1.2 (Tesfaye Megerssa Oljira, 2019) We shall say that the mapping $S$ is f-non-decreasing (resp. f-non-increasing) if $f x \preccurlyeq f y \Rightarrow S x \preccurlyeq S y$ (respectively $f x \preccurlyeq f y \Rightarrow S y \preccurlyeq S x$ ) holds for each $x, y \in X$.

Definition 1.3 (Akram and Shamailac, 2015) A point $y \in X$ is called point of coincidence of two mappings $f, S: X \rightarrow X$ if there exists a point $x \in X$ such that $y=f x=S x$. In this case $x$ is called the coincidence point of $f$ and $S$ and the set of coincidence points of $f$ and $S$ is denoted by $C(f, S)$. If $x=y$, then $y$ is called common fixed point of $f$ and $S$.

Definition 1.4 (Pant et al., 2012) Let $f$ and $S$ be self maps of a metric space $(X, d)$. The pair $(f, S)$ is called occasionally weakly compatible (OWC) if there exists $x \in X$ which is a coincidence point for $f$ and $S$ at which $f$ and $S$ commute (i.e. if $f(S(x))=$ $S(f(x))$ for some $x \in C(f, S))$.

Theorem 1.1( $\mathrm{Su}, 2014) \operatorname{Let}(\mathrm{X}, \preccurlyeq)$ be a partially ordered set and suppose that there exists a metric $d$ onX such that $(\mathrm{X}, \mathrm{d})$ is a complete metric space. Let $\mathrm{T}: \mathrm{X} \rightarrow \mathrm{X}$ be a continuous and non-decreasing mapping such that
$\eta(d(T x, T y)) \leq \phi(d(x, y)), \forall y \preccurlyeq \mathrm{x}$,
where $\eta$ is a generalized altering distance function and $\phi:(0, \infty) \rightarrow(0, \infty)$ is a right upper semi-continuous function with the condition: $\eta(t)>\phi(t)$ for all $t>0$. If there exists $x_{0} \in X$ such that $x_{0} \leqslant T x_{0}$, then $T$ has a fixed point.

If $\left(x_{n}\right)$ is a non-decreasing sequence in $X$ such that $x_{n} \rightarrow x$ then $x_{n} \leqslant x$ for all $n \in \mathbb{N}$. (a)
Theorem $1.2(\mathrm{Su}, 2014)$ Let $(\mathrm{X}, \preccurlyeq)$ be a partially ordered set and suppose that there exists a metric d in X such that ( $\mathrm{X}, \mathrm{d}$ ) is a complete metric space. Assume that $X$ satisfies (a). Let T : X $\rightarrow \mathrm{X}$ be a continuous and non-decreasing mapping such that
$\eta(d(T x, T y)) \leq \phi(d(x, y)), \forall y \leqslant \mathrm{x}$,
where $\eta$ is a generalized altering distance function and $\phi:(0, \infty) \rightarrow(0, \infty)$ is a right upper semi-continuous function with the condition: $\eta(t)>\phi(t)$ for allt $>0$. If there exists $x_{0} \in X$ such that $x_{0} \leqslant T x_{0}$, then T has a fixed point.
for $x, y \in X$ there exists $z \in X$ which is comparable to $x$ and $y$
Theorem 1.3 ( $\mathrm{Su}, 2014$ ) Adding the condition (b) to the hypothesis of Theorem 1.1 (resp. Theorem 1.2) we obtain the uniqueness of the fixed point of $T$.

Theorem 1.4 (Tesfaye Megerssa Oljira, 2016) Let $(X, \preccurlyeq)$ be a partially ordered set and suppose that there exists a metric $d$ on $X$ such that $(X, d)$ is a complete metric space. Let $f, T: X \rightarrow X$ be two continues self maps on $X$ satisfying the following conditions:
i) $T X \subset f X$;
ii) $f X$ is closed;
iii) $T$ is f-non-decreasing;
iv) There exists $x_{0} \in X$ such that $f x_{0} \leqslant T x_{0}$;
v) If $z \in C(f, T)$, then $f z \preccurlyeq f(f z)$ such that $\eta(d(T x, T y)) \leq \phi(d(f x, f y)) \forall x, y \in X$ with $f y \preccurlyeq f x$, where $\eta$ is an altering distance functions and $\phi:(0, \infty) \rightarrow(0, \infty)$ is a right uppersemi-continuous function with the condition $\eta(t)>\phi(t)$ for all $t>$ 0 and $\phi(t)=0 \Leftrightarrow t=0$. Then $f$ and $T$ have a coincidence point. Furthermore if $f$ and $T$ are occasionally weakly compatible maps, then $f$ and $T$ have common fixed point in $X$.

## 2. MAIN RESULT

Assuming the following hypothesis in $X$ :
If $\left\{y_{n}\right\}$ is a non-decreasing sequence in $X$ such thaty $y_{n} \rightarrow$ ythen $y_{n} \leqslant y$ for all $n \in \mathbb{N}$.(1)
Theorem 2.1 Let $(X, \preccurlyeq)$ be a partially ordered set and suppose that there exists a metric $d$ on $X$ such that $(X, d)$ is a complete metric space. Assume that $X$ satisfies (1). Let $f, T: X \rightarrow X$ be two self maps satisfying the following conditions:
i) $T X \subset f X$;
ii) $f X$ is closed;
iii) $T$ is f-non-decreasing;
iv) there exists $x_{0} \in X$ such that $f x_{0} \leqslant T x_{0}$;
v)if $z \in C(f, T)$, then $f z \preccurlyeq f(f z)$
such that
$\eta(d(T x, T y)) \leq \phi(d(f x, f y)) \forall x, y \in X$ with $f y \preccurlyeq f x$,
where $\eta$ isan altering distance functions and $\phi:(0, \infty) \rightarrow(0, \infty)$ is a right upper semi-continuous function with the condition $\eta(t)>\phi(t)$ for all $t>0$. Then $f$ and $T$ have a coincidence point. Furthermore if $f$ and $T$ are occasionally weakly compatible maps, then $f$ and $T$ have common fixed point.

Proof Suppose there exists $x_{0} \in X$ such that $f x_{0} \leqslant T x_{0}$. Since $T X \subset f X$, we can choose $x_{1} \in X$ such that $f x_{1}=T x_{0}$. Again from $T X \subset f X$, we can choose $x_{2} \in X$ such that $f x_{2}=T x_{1}$. Continuing this process, we can choose a sequence $\left\{y_{n}\right\}$ in $X$ such that
$y_{n}=f x_{n+1}=T x_{n}, \quad \forall n \geq 0$.
By similar procedure we followed in Theorem 1.4, we can show that the sequence $\left\{y_{n}\right\}$ is a Cauchy sequence in $X$. Since $(X, d)$ is a complete metric space and using (2), $\left\{y_{n}\right\} \subset f(X)$ where $y_{n}=f x_{n+1}$ for each $n \geq 1$ and $f(X)$ is closed, then there exists $p \in X$ such that $y=f p$. Now we prove that $T p=y$. Then, by the continuity of $\eta$ and the upper semi-continuity of $\phi$, using the condition (2), we have
$\eta(d(T p, y))=\eta\left(d\left(T p, \lim _{n \rightarrow \infty} T x_{n}\right)\right)$
$=\lim _{n \rightarrow \infty} \eta\left(d\left(T p, T x_{n}\right)\right)$
$\leq \lim _{n \rightarrow \infty} \phi\left(d\left(f p, f x_{n}\right)\right)$
$\leq \lim _{n \rightarrow \infty} \eta\left(d\left(f p, f x_{n}\right)\right)$
$=\eta\left(\lim _{n \rightarrow \infty} d\left(f p, f x_{n}\right)\right)$
$=\eta\left(d\left(f p, \lim _{n \rightarrow \infty} f x_{n}\right)\right)$
$=\eta(d(f p, f p))=\eta(0)=0$.

This implies that $\eta(d(T p, y))=0$ and hence $T p=y$.
Thus
$y=T p=f p$.
This implies that $\eta(d(T p, y))=0$ and hence $T p=y$.
Thus
$y=T p=f p$
Thus $p$ is the coincidence point of $f$ and $T$, which implies that $C(f, T) \neq \emptyset$. Since $f$ and $T$ are occasionally weakly compatible pair of self maps, $f$ and $T$ commute at some point $z \in C(f, T)$.

Now set $w=f z=T z$. Since $f$ and $T$ are occasionally weakly compatible,
$f w=T w$.
Now we claim that $w$ is a common fixed point of $f$ and $T$.
Now if $T w \neq w$, since by (v) of Theorem 2.1, $f z \preccurlyeq f(f z)=f w$, we have
$\eta(a(I w, w))=\eta(a(I w, I z)) \leq \phi(a(f w, f Z)) \leq \phi(a(I w, w))<\eta(a(I w, w))$,
which is absurd. Hence, $T w=w$.

Therefore $f w=T w=w$.
Example 2.1.1 Let $X=\{1,2,3,4,5\}$. We define a partial order " $\preccurlyeq$ " on $X$ by
$\preccurlyeq=\{(1,1),(2,2),(3,3),(4,4),(5,5),(2,3),(3,4),(2,4)\}$.
Define a metric $d: X \times X \rightarrow \mathbb{R}$ by $d(x, y)=|x-y|$ for all $x, y \in X$.

Consider the mappings $f, T: X \rightarrow X$ defined by
$f(1)=1, f(2)=2, f(3)=2, f(4)=3, f(5)=4$ and
$T(1)=1, T(2)=2, T(3)=2, T(4)=2, T(5)=2$.
Then $T(X)=\{1,2\} \subset\{1,2,3,4\}=f(X)$ and $f(X)=\{1,2,3,4\}$ is closed.
Next we show that $T$ is f-non-decreasing.
$2=f(2) \preccurlyeq f(4)=3 \Rightarrow 2=T(2) \leqslant T(4)=2$
$2=f(3) \preccurlyeq f(4)=3 \Rightarrow 2=T(3) \leqslant T(4)=2$;
$3=f(4) \leqslant f(5)=4 \Rightarrow 2=T(4) \leqslant T(5)=2$;
$2=f(2) \preccurlyeq f(5)=4 \Rightarrow 2=T(2) \leqslant T(5)=2$;
$2=f(3) \preccurlyeq f(5)=4 \Rightarrow 2=T(3) \preccurlyeq T(5)=2$
which shows that $T$ is f-non-decreasing. We also observe that $f(1) \preccurlyeq T(1)$ and $z=2 \in C(f, T)=\{1,2,3\}$ such that $f z \preccurlyeq f(f z)$. Further, $f$ and $T$ satisfy all the contraction conditions of Theorem 2.1 for $\eta(t)=t$ and $\phi(t)=\frac{1}{2} t, t \geq 0$. Since $C(f, T) \neq \emptyset, f$ and $T$ are occasionally weakly compatible maps. Moreover, 1 and 2 are common fixed points of $f$ and $T$. Hence the uniqueness of common fixed point of $f$ and $T$ is not guaranteed by the conditions of Theorem 2.1. Remark 1By choosing a map $T$ to be nondecreasing and $f=$ Identity map in Theorem 2.1 we get Theorem 1.2 as a corollary to Theorem 2.1.

Lemma 2.1. (Pant et al., 2012) Let $X$ be a non-empty set, $f$ and $T$ are occasionally weakly compatible self maps of $X$. If $f$ and $T$ have a unique point of coincidence, $w=f x=T x$ then $w$ is the unique common fixed point of $f$ and $T$.

Proof: Let $z$ be a unique point of coincidence of $f$ and $T$. Then $z=f x=T x$ for some $x \in X$ which implies that $C(f, T) \neq \emptyset$. Now since $f$ and $T$ are occasionally weakly compatible maps, $f T(u)=T f(u)$ for some $u \in C(f, T)$. So, by the uniqueness of $z$, we have $z=f u=T u$ and hence $f z=f T(u)=T f(u)=T z$, which again follows that $z=f z=T z$. Thus, $z$ is a common fixed point of $f$ and $T$. Suppose now that there exists another common fixed point $w \in X$ of $f$ and $T$.

Then $w$ becomes a point of coincidence of $f$ and $T$. Consequently, by the uniqueness of point of coincidence we obtain, $w=z$. In what follows, we give sufficient condition for the uniqueness of common fixed point of $f$ and $T$ in Theorems 1.4 and Theorem 2.1? Theorem 2.2. In addition to the hypothesis of Theorem 1.4 and Theorem 2.1, suppose that $f: X \rightarrow X$ is non-decreasing and for every $x, y \in X$ there exists $z \in X$ which is comparable to $x$ and $y$. Then $f$ and $T$ have a unique common fixed point in $X$.

Proof by Theorem 2.1, the set of common fixed points of $f$ and $T$ is non-empty.
Suppose that there exist $y, z \in X$ which are common fixed points of $f$ and $T$. We consider two cases.
Case 1.If $y$ is comparable toz, then $y=T y$ is comparable toz $=T z$. So,
$\eta(d(y, z))=\eta(d(T y, T z)) \leq \phi(d(f y, f z))=\phi(d(y, z))$.
As the condition $\eta(t)>\phi(t)$ for $t>0$, we obtain $d(y, z)=0$ which in turn implies $y=z$.

Case 2.If $y$ is not comparable to $z$, then there exists $x_{0} \in X$ which is comparable to $y$ and $z$; i.e., either $x_{0} \leqslant y$ and $x_{0} \leqslant z$ or $y \preccurlyeq$ $x_{0}$ and $z \preccurlyeq x_{0}$.

Without loss of generality let us take $y \preccurlyeq x_{0}$ and $z \preccurlyeq x_{0}$.
Now $x_{0} \leqslant y \Rightarrow f x_{0} \leqslant f y$, since $f$ is non-decreasing on $X$.

But $T X \subset f X$. Then there exists $x_{1} \in X$ such that $T x_{0}=f x_{1}$. It follows that
$f x_{1} \preccurlyeq y=f y$.
Since T is $f$-non-decreasing on $X$, this implies
$T x_{1} \preccurlyeq T y=y$.
Now again since $T X \subset f X$, there exists $x_{2} \in X$ such that $T x_{1}=f x_{2}$. This implies
$f x_{2} \preccurlyeq y=f y$
Proceeding this way, inductively we construct a sequence $\left\{p_{n}\right\}$ such that $\forall n \geq 0$,
$p_{n} \preccurlyeq y$,
where $p_{n}=T x_{n}=f x_{n+1}$ for each $n=0,1,2, \cdots$.
If there exists $N \in \mathbb{Z}^{+}$such that $y=p_{N}$, then
$\eta\left(d\left(y, p_{N+1}\right)\right)=\eta\left(d\left(T y, T x_{N+1}\right)\right) \leq \phi\left(d\left(f y, f x_{N+1}\right)\right)=\phi\left(d\left(y, p_{N}\right)\right)=0$,
which implies that $y=p_{n}, \forall n \geq N$ and hence the sequence $\left\{p_{n}\right\} \rightarrow y$ as $n \rightarrow \infty$.
Suppose that $y \neq p_{n}, \forall n \geq 0$. Then
$\eta\left(d\left(y, p_{n}\right)\right)=\eta\left(d\left(T y, T x_{n}\right)\right) \leq \phi\left(d\left(f y, f x_{n}\right)\right)=\phi\left(d\left(y, p_{n-1}\right)\right)$
which implies that
$\eta\left(d\left(y, p_{n}\right)\right) \leq \phi\left(d\left(y, p_{n-1}\right)\right)<\eta\left(d\left(y, p_{n-1}\right)\right), \forall n=1,2,3, \cdots$.
From the property of $\eta$, we notice that $\left\{d\left(y, p_{n}\right)\right\}$ is a non-decreasing sequence and hence there exists $b \geq 0$ such that
$d\left(y, p_{n}\right) \rightarrow b$ as $n \rightarrow \infty$.
We claim that $b=0$.
Letting $n \rightarrow \infty$ in (4) and taking into account the properties of $\eta$ and $\phi$, we obtain $\eta(b) \leq \phi(b)$. This and the condition $\eta(t)>$ $\phi(t)$ for $t>0$ imply $b=0$. Hence,
$\lim _{n \rightarrow \infty} d\left(y, p_{n}\right)=0$.
In similar line, it can be proved that
$\lim _{n \rightarrow \infty} d\left(z, p_{n}\right)=0$.
Finally, as
$\lim _{n \rightarrow \infty} d\left(y, p_{n}\right)=\lim _{n \rightarrow \infty} d\left(z, p_{n}\right)=0$,
by the uniqueness of limit of a convergent sequence in metric spaces we obtain $y=z$. This completes the proof.
Remark 2 by choosing $T$ to be f-non-decreasing map in Theorem 2.2, we get Theorem 1.3 as a corollary to Theorem 2.1.The following is an example in support of Theorem 2.2.

Example 2.2.1. Let $X=[-3,3]$ and define order relation "ß" on $X$ by
$x \leqslant y \Leftrightarrow\{(x=y)$ or $(x \in[-3,0] \& y \in[0,3])\}$.
We observe that $(X, \preccurlyeq)$ is partially ordered set.

Denme $u: \Lambda \times \Lambda \rightarrow \mathbb{K}$ dy $u(x, y)=|x-y| \nabla x, y \in \Lambda$.
Consider the mapping $f, T: X \rightarrow X$ defined by $T x=\frac{x}{3}$ and $f x=\frac{x}{2}$. Define $\eta, \phi:[0, \infty) \rightarrow(0, \infty)$ by $\eta(t)=\left\{\begin{array}{l}\frac{11}{60} t, 0 \leq t<1 \\ \frac{1}{5} t, t \geq 1\end{array}\right.$ and $\phi(t)=\frac{1}{6} t$. Then $\eta$ and $\phi$ satisfy the conditions of the theorem. Here we observe that $T(X)=[-1,1] \subset\left[-\frac{3}{2}, \frac{3}{2}\right]=f(X)$ and $f(X)=\left[-\frac{3}{2}, \frac{3}{2}\right]$ is closed in $X$.

Now if $x, y \in X$ such that $f x \preccurlyeq f y$, then either $f x=f y$ or $f x \in[-3,0]$ and $f y \in[0,3]$.
$\Rightarrow x=y$ or $x \in[-3,0]$ and $y \in[0,3] .\left(\because f x, f y \in f([-3,3])=\left[\frac{-3}{2}, \frac{3}{2}\right]\right)$
$\Rightarrow T x=T y$ or $T x \in[-3,0]$ and $T y \in[0,3]$
$\Rightarrow T x \preccurlyeq T y$
Clearly there exists $x_{0}=0 \in[-3,3]$ such that $f x_{0}=T x_{0}$,
i.e., $f x_{0} \leqslant T x_{0}$.

Also, $f$ is a non-decreasing, since if $x, y \in \mathrm{X}$ such that $x \preccurlyeq y$, then either $x=y$ or $x \in[-3,0]$ and $y \in[0,3]$
$\Rightarrow f x=f y$ or $f x=\frac{x}{2} \in[-3,0]$ and $f y=\frac{y}{2} \in[0,3]$
$\Rightarrow f x \leqslant f y$
Now let $x, y \in[-3,3]$ such that $f x \preccurlyeq f y$. Then either $f x=f y$ or $f x \in[-3,0]$ and $f y \in[0,3]$.
Case (i) If $f x=f y$, we have $\frac{x}{2}=\frac{y}{2}$, which implies $T x=T y$ and hence obviously the inequality (2) hold.
Case (ii) If $f x \in[-3,0]$ and $f y \in(0,3)$, then $\frac{x}{2} \in(-3,0)$ and $\frac{y}{2} \in(0,3)$.
This implies that
$x \in[-3,0]$ and $y \in(0,3)$ (Since $\left.f x, f y \in f([-3,3])=\left(-\frac{3}{2}, \frac{3}{2}\right)\right)$.
Now we shall consider two sub-cases
If $0 \leq y-x<1$, then
$\eta(d(T x, T y))=\eta\left(\frac{1}{3}(y-x)\right) \leq \phi\left(\frac{1}{3}(y-x)\right)=\phi(d(f x, f y))$.
Ify $-x \geq 1$, then
$\eta(d(T x, T y))=\eta\left(\frac{1}{3}(y-x)\right) \leq \phi\left(\frac{1}{3}(y-x)\right)=\phi(d(f x, f y))$.
Thus
$\eta(d(T x, T y)) \leq \phi(d(f x, f y)) \forall x, y \in X$ with $f x \preccurlyeq f y ;$
For
$\eta(t)=\left\{\begin{array}{l}\frac{11}{60} t, 0 \leq t<1 \\ \frac{1}{5} t, t \geq 1\end{array}\right.$ and $\phi(t)=\frac{1}{6} t$.
Thus, $f$ and $T$ satisfy all the conditions of Theorem 1.4 and Theorem 2.1. Moreover, 0 is a unique common fixed point of $f$ and $T$.
